Path of input files Path of output files Name of output file PATH Value: Folder input/output can be specified for 1 file. But if 2 or more files are specified then they will be merged together so that the output directory has exactly one file. NAME value: Unique name for each output file. TIFFSplit will select the best image to split at any sub-section. When a split is requested it will, if it can, load all the images into memory. A warning will appear if a file contains a known image cannot be recognised or if the image exceeds any of the defined maximum sizes. The program will split only the first image it recognises. When the program is opened it checks the input and output folders to see if they exist and if they do then it will check them to see if they contain tiffs. If not the program will prompt the user to specify the path to the input and output folders. When the program starts it will select the input and output folders by prompting the user for the full path name. The application will start searching the input folder looking for any tiffs it finds, if it finds one it will load it and ask the user if the tiff can be split. If the tiff can be split then the program will split the tiff then if the tiff can be split again then it will split again and so on until the tiff cannot be split any more. If a tiff can be split and then cannot be split again then the program will prompt the user for a new split value. This is a recursive program. One of the best ways to split a tiff is to have a look through it with a magnifier and then save it as a new tiff. Once the program has loaded all the files in memory it will then search through the folder for any tiffs it can find, if it can't find one then it will prompt the user for a new folder and search again. The program then will search through all the tiffs it can find and split them. It will then check if the tiff it split can be split again 77a5ca646e
