An MRI-based porcine myocardial viability map. Myocardial viability is known to be a risk factor for future heart failure following acute myocardial infarction. MRI offers great potential for myocardial viability mapping. However, the evaluation of the spatial distribution of myocardial infarction within the heart is complicated by the presence of noninfarcted myocardium. A viable myocardial viability map, which can be directly derived from MRI data, was created for evaluating the spatial distribution of myocardial viability. The viability map was generated by segmenting the endocardium of the left ventricle, and three different methods were used to assign infarcted tissue, and noninfarcted and viable tissue based on T2-weighted and T2\*-weighted images. A myocardial viability map was generated based on the segmentation results. The viability map revealed the spatial distribution of myocardial infarction within the heart. Furthermore, the viability map was used to investigate the relationship between the extent of myocardial infarction and the development of heart failure after myocardial infarction.

Q: Efficiently finding neighbours in C++ I have a C++ class called Element. The constructor takes in two integers representing an element and two integers representing the number of neighbours on each side. For instance, say I have [1,2,3,4,5] and 5 neighbours on each side. I would have 5(neighbours). When a neighbor is found, I want to make a new array to store the element, the index, and its neighbours. The index would be an array of the same size of the element with the neighbour inside it, for instance [1,2,5,3] is one element and [1,5,2,3] is another. For the next neighbour, this array would then be duplicated, and its neighbour then pushed onto that array. The next neighbour would then be placed
